# 1 Big picture

- **Question.** Do domestic and foreign political risks increase stock-return volatility, and do some industries react more strongly to political risk than others?
- **Setting.** The paper studies publicly listed firms in **50 countries** over **1990–2006**. The unit of analysis is mainly a two-digit SIC **industry–country–year** observation.
- **Core idea.** Political events do not affect all industries equally. The paper therefore measures industries’ **political sensitivity** along three dimensions:
  - dependence on **international trade**,
  - dependence on **contract enforcement**, and
  - **labor intensity**.
- **Main empirical design.** The paper interacts industry-level political sensitivities with country-level political variables such as elections, autocracy, political risk, left-party government, and labor-law rigidity.
- **Why industry-level analysis matters.** Aggregate country regressions often fail to detect the political-volatility channel because political shocks have heterogeneous effects across sectors. The paper’s design asks whether politically exposed sectors become more volatile *relative to other sectors in the same broad environment*.
- **Main results.**
  - More export-oriented industries are more volatile when domestic or foreign political risk is high.
  - Foreign political risk matters especially for **idiosyncratic** volatility of trade-dependent industries.
  - Domestic political risk matters especially for **systematic** volatility.
  - Industries that rely more on complex input relationships, and hence on contract enforcement, are more volatile during domestic elections and high political risk.
  - Labor-intensive industries are more volatile under left governments and in countries with stricter labor regulations.
  - Autocratic regimes tend to dampen volatility for industries exposed to trade and contract enforcement, consistent with a “stability” effect of entrenched political arrangements.
- **Economic takeaway.** Political risk is not just a country-level background variable. It is transmitted into asset-market volatility through concrete industry channels: trade links, contracting needs, and labor regulation.

## 2 Data and measurement (key objects)

### 2.1 Observed firm, industry, and country data

- **Stock-return data.** Firm return data come from **Datastream**; accounting and industry information come from **Worldscope**.

- **Sample period.** The main volatility sample covers **1990–2006**.
- **Country coverage.** The paper studies firms in **50 countries**, including both developed and developing economies.
- **Industry definition.** Industries are defined at the **two-digit SIC** level. The primary sample contains **57 SIC industries**.
- **Firm inclusion rule.** A firm must have at least **26 weeks** of return data in a year.
- **Outlier treatment.** Weekly returns below  $-75\%$  or above  $+75\%$  are dropped. Volatility measures are winsorized at the 1st and 99th percentiles.
- **Scale of the dataset.** The main return-volatility sample contains **26,429 industry–country–year observations**, based on **286,433 firm-year observations**.

## 2.2 Return volatility measures

- The dependent variable is the log of annualized industry return volatility.
- For firm  $f$ , weekly return volatility is computed as

$$\sigma_f = \left[ \frac{1}{W-1} \sum_{w=1}^W \left( r_{f,w} - \frac{1}{W} \sum_{w=1}^W r_{f,w} \right)^2 \right]^{1/2}.$$

- Industry volatility is the average of firm volatilities within an industry:

$$\sigma_{ind} = \frac{1}{F_{ind}} \sum_{f=1}^{F_{ind}} \sigma_f.$$

- The paper also decomposes volatility into systematic and idiosyncratic parts using a two-factor model:

$$r_{f,w} = \alpha_f + \beta_{1,f} r_{world,w} + \beta_{2,f} r_{country,w} + \varepsilon_{f,w}.$$

- **Systematic volatility** is the standard deviation of the explained component of returns.
- **Idiosyncratic volatility** is the standard deviation of the residual component  $\varepsilon_{f,w}$ .
- For election years, the volatility window is centered on the election date: 26 weeks before and 26 weeks after the election.

## 2.3 Industry political sensitivity measures

- **International trade exposure.** This is the share of industry sales exported to foreign markets. Export data come from UNCTAD/WTO PC-TAS, and sales data come from the United Nations Industrial Commodity Production Statistical database.
- For industry  $ind$  in country  $c$ , exports to trading partner  $j$  in year  $t$  are scaled by sales:

$$\text{TRADE}_{ind,j,t}^c = \frac{\text{EXP}_{ind,j,t}^c}{\text{SALES}_{ind,t}^c}.$$

- Total export exposure is

$$\text{TRADE}_{ind,t}^c = \sum_j \text{TRADE}_{ind,j,t}^c.$$

- **Contract enforcement sensitivity.** This measures how complex an industry's input structure is. The idea is that industries using many different inputs rely more on contract enforcement.
- The measure is one minus the Herfindahl index of industry input shares:

$$C_{ind} = 1 - \sum_k \phi_{ind,k}^2,$$

where  $\phi_{ind,k}$  is the share of input from industry  $k$  used by industry  $ind$ .

- **Labor intensity.** This is the value of labor inputs divided by total input value:

$$LI_{ind,t} = \frac{v_{ind,t}^l}{v_{ind,t}^l + v_{ind,t}^k + v_{ind,t}^e + v_{ind,t}^m},$$

where the denominator includes labor, capital services, energy, and materials.

- Contract enforcement sensitivity and labor intensity are mostly constructed from U.S. input-output or production data and then applied across countries. This is meant to capture technological features of industries rather than country-specific institutional responses.

## 2.4 Country political variables

- **National elections.** A dummy equal to one in years with presidential elections in presidential systems or parliamentary elections in parliamentary systems.
- **Autocracy.** Based on the POLITY score. The paper transforms the original scale so that higher values mean more autocratic regimes.
- **Political risk.** Based on the International Country Risk Guide index. The paper transforms the index so that higher values mean greater political risk.
- **Party orientation.** A dummy equal to one when the chief executive's party is classified as left-wing.
- **Rigidity of employment.** A World Bank Doing Business index, available for 2004–2006, where higher values indicate more rigid employment regulation.

## 2.5 Descriptive facts

- Average trade exposure across countries, industries, and years is about **5.44%**.
- Some industries are highly trade-exposed: electronic and electrical equipment has trade exposure of about **16.64%**; industrial and computer equipment has about **9.57%**.
- Some industries have very low trade exposure: building materials is about **2.41%**, and electric, gas, and sanitary services is about **2.28%**.
- Average contract enforcement sensitivity is about **0.841**. Building construction has a high score because it uses many different inputs.
- Average labor intensity is about **0.275**. Petroleum refining is very low at about **0.057**; measuring instruments is high at about **0.501**; hotels are also high at about **0.481**.

## 2.6 Controls and timing

- The regressions include industry, country, and year fixed effects.
- Country controls include GDP per capita, law-and-order quality, exchange-rate risk, financial development, and ownership concentration.
- Industry controls include size, leverage, diversification, equity dependence, and skill dependence.
- The paper also includes interactions between political variables and relevant controls to reduce concerns that political sensitivity is proxying for economic development, legal quality, or exchange-rate instability.

## 3 Models and empirical specifications (all equations + interpretation)

### 3.1 Main panel specification

The main regression is

$$LVOL_{ind,t}^c = \alpha_{ind} + \delta_c + \eta_t + \beta \left( \text{SENSITIVITY}_{ind,t}^c \times \text{POLITICAL}_t^c \right) + \gamma \text{POLITICAL}_t^c + \lambda \text{SENSITIVITY}_{ind,t}^c + \text{CONTROLS}_{ind,t}^c$$

- $LVOL_{ind,t}^c$  is the log of annualized volatility for industry  $ind$ , country  $c$ , and year  $t$ .
- $\alpha_{ind}$  are industry fixed effects.
- $\delta_c$  are country fixed effects.
- $\eta_t$  are year fixed effects.
- SENSITIVITY is one of the industry exposure measures: trade exposure, contract enforcement sensitivity, or labor intensity.
- POLITICAL is one of the political variables: elections, autocracy, political risk, left-party orientation, or labor-law rigidity.
- The coefficient of interest is  $\beta$ .

**Interpretation.** The coefficient  $\beta$  asks: when a country experiences a given political condition, do industries that are more exposed to that political channel become differentially more volatile?

### 3.2 Trade exposure and domestic politics

For domestic politics, the key interaction is

$$\text{TRADE}_{ind,t}^c \times \text{POLITICAL}_t^c.$$

- If  $\beta > 0$ , trade-dependent industries are more volatile when domestic political uncertainty is higher.
- A positive coefficient can arise because export subsidies, licenses, trade policy, or regulatory support become more uncertain around elections or in risky political environments.

- A negative coefficient with autocracy can arise if autocratic governments provide stable support to favored export sectors.

**Interpretation.** Export exposure is not only an international-demand channel. It can also make firms sensitive to domestic political decisions that affect their ability to sell abroad.

### 3.3 Trade exposure and global politics

The paper also constructs a trading-partner-weighted global political exposure:

$$\text{GLOBALPOL}_{ind,t}^c = \sum_j \left( \text{TRADE}_{ind,j,t}^c \times \text{POLITICAL}_{j,t} \right).$$

- This variable is large when an industry exports heavily to countries that are experiencing elections, high political risk, or autocracy.
- It separates foreign political risk from home-country political risk.
- The idea is that firms relying on exports to politically risky destinations face more uncertain foreign demand, payment, regulation, or contract conditions.

**Interpretation.** Trade can diversify away domestic demand risk, but it also imports political risk from trading partners.

### 3.4 Contract enforcement channel

The contract-enforcement specification uses

$$C_{ind} \times \text{POLITICAL}_t^c,$$

where

$$C_{ind} = 1 - \sum_k \phi_{ind,k}^2.$$

- A high value of  $C_{ind}$  means that production uses inputs from many different supplying industries.
- Such industries are more vulnerable to weak institutions because more supplier relationships must be governed by contracts.
- Elections and political risk may disrupt contract enforcement or change the perceived stability of institutional arrangements.

**Interpretation.** Political risk affects firms not only through demand or policy but also through the reliability of contracting relationships inside the production process.

### 3.5 Labor intensity channel

The labor-channel regressions use interactions such as

$$LI_{ind,t} \times \text{LeftParty}_t^c,$$

$$LI_{ind,t} \times \text{Election}_t^c,$$

and

$$LI_{ind,t} \times \text{EmploymentRigidity}_t^c.$$

- Left parties are expected to support more labor-friendly and redistributive policies.
- Stricter labor regulation can make it harder for firms to adjust employment after negative shocks.
- Therefore labor-intensive industries should have more volatile cash flows and stock returns when labor policy is more restrictive or uncertain.

**Interpretation.** The political risk here operates through factor-market rigidity: if labor adjustment is costly, negative shocks have a larger effect on profits.

### 3.6 Volatility decomposition

The paper estimates all main specifications using three dependent variables:

$$LVOL_{ind,c,t}^{Total}, \quad LVOL_{ind,c,t}^{Idio}, \quad LVOL_{ind,c,t}^{Sys}.$$

- **Total volatility** captures the overall instability of industry returns.
- **Idiosyncratic volatility** captures volatility not explained by world and country market factors.
- **Systematic volatility** captures the component explained by global and domestic market indexes.

**Interpretation.** This decomposition is central because the paper finds that global political risk is mainly connected to idiosyncratic volatility, while domestic political risk is more connected to systematic volatility.

### 3.7 Endogeneity and robustness specifications

The paper addresses several endogeneity concerns:

- **Autocracy and political risk.** The authors use instrumental variables based on settlers' mortality and ethnolinguistic fractionalization.
- **Elections.** They separate fixed-timing elections from flexible-timing and early elections to check whether results are driven by endogenous election timing.
- **Left-party orientation.** They decompose left-party orientation into an explained part and an unexplained part using lagged macro variables.
- **Political crises.** They interact industry sensitivities with a political-crisis dummy as another test of political shocks.
- **Alternative volatility measures.** They reweight firm volatility by assets, debt, and diversification, and also examine pure-play firms.
- **Fundamental volatility.** They control for ROA volatility to check whether results are purely driven by volatility of fundamentals.

- **Alternative labor intensity.** They use country-specific labor intensity from Worldscope, measured as employees divided by sales.

**Interpretation.** The robustness tests are designed to show that the results are not just artifacts of country-level omitted variables, election timing, volatility construction, or U.S.-based industry measures.

## 4 Identification and instruments (what makes the estimates credible)

### 4.1 Why aggregate country regressions are not enough

- A simple regression of country volatility on elections or political risk is hard to interpret because political risk is correlated with macroeconomic conditions, financial development, institutions, and crises.
- The paper shows that some aggregate comparisons are weak: average volatility is not significantly different during election years versus nonelection years, nor under left governments versus other governments.
- Aggregate country-level tests can miss political effects if only some industries are exposed to the relevant political channel.

### 4.2 Rajan–Zingales-style industry sensitivity design

- The identifying variation comes from whether politically sensitive industries become more volatile when the relevant country political variable is high.
- Industry fixed effects absorb time-invariant differences across industries, such as naturally high volatility in technology or mining.
- Country fixed effects absorb time-invariant differences across countries, such as persistent differences in financial development or legal origins.
- Year fixed effects absorb global shocks common to all countries and industries.
- The interaction design therefore focuses on **differential within-country industry responses** to political risk.

**Core identifying assumption.** Conditional on controls and fixed effects, industries with higher measured political sensitivity would not have become differentially more volatile in politically risky country-years for reasons unrelated to the proposed political channel.

### 4.3 Why the three channels are informative

- **Trade exposure** identifies exposure to domestic and foreign political uncertainty because export-dependent industries rely on cross-border regulations, foreign demand, and trading-partner stability.

- **Contract enforcement sensitivity** identifies exposure to institutional quality because input-complex industries rely on many supplier relationships.
- **Labor intensity** identifies exposure to labor politics because labor-intensive industries are more affected by firing costs, hiring restrictions, and redistributive labor policy.

#### 4.4 Domestic versus global political risk

- A distinctive feature of the paper is that it separates home-country political risk from trading-partner political risk.
- This is possible because the authors observe industry-level exports to specific destinations.
- Foreign political variables are weighted by export shares, so the same home-country industry can have different global political exposure depending on where it sells its output.

**Interpretation.** This lets the paper show that trade is not simply a diversification device. It can transmit foreign political shocks into domestic equity volatility.

#### 4.5 Instrumental variables and endogeneity checks

- For autocracy and political risk, the paper uses **settlers' mortality** and **ethnolinguistic fractionalization** as instruments.
- For election timing, the paper checks whether results differ between fixed-timing elections, flexible-timing elections, and early elections.
- For left-party orientation, the paper first predicts left-party government using lagged macro variables and then studies whether the unexplained component still matters.
- For political crises, the paper uses a crisis dummy based on 46 political disruptions across 18 countries.

**Interpretation.** These checks do not turn the design into a perfect experiment, but they address the most obvious concerns that economic volatility itself may cause political variables.

#### 4.6 Limitations

- The paper does not include country-year fixed effects because the political variables vary at the country-year level and would be absorbed.
- Some omitted country-year shocks could still matter if they affect high-sensitivity industries differently.
- Industry sensitivities measured from U.S. data may not perfectly describe production technologies in all countries.
- The paper studies volatility, not expected returns, so it does not directly test whether political risk is priced.

## 4.7 Relation to the literature

- The paper contributes to the literature on politics and financial markets by showing that routine political processes, not just coups, wars, and crises, affect return volatility.
- It contributes to international finance by showing that trade linkages transmit foreign political risk.
- It contributes to the industry-level finance literature by identifying business characteristics that shape systematic and idiosyncratic volatility.

## 5 Tables and figures

### 5.1 Table 1: variables, definitions, and sources

Read:

- Table 1 is the measurement map of the paper.
- It defines the three volatility outcomes: total, idiosyncratic, and systematic volatility.
- It also defines the three industry political-sensitivity measures: international trade exposure, contract enforcement sensitivity, and labor intensity.
- The political variables are carefully transformed so that higher values mean more autocracy or more political risk.
- The table also lists the main controls, including exchange-rate risk, law efficiency, GDP per capita, industry size, leverage, diversification, equity dependence, financial development, skill dependence, and ownership concentration.

### 5.2 Table 2: descriptive statistics by industry and country

**Table 2**  
Descriptive statistics

Panel A: Descriptive statistics by industry

| Industry name                 | SIC code | Total volatility | Idiosyncratic volatility | Systematic volatility | International trade exposure (%) | Sensitivity to contract enforcement | Labor intensity | Number of country-years | Number of firm-years |
|-------------------------------|----------|------------------|--------------------------|-----------------------|----------------------------------|-------------------------------------|-----------------|-------------------------|----------------------|
| Agricultural crops            | 100      | 0.444            | 0.408                    | 0.148                 | 5.03                             | —                                   | 0.245           | 319                     | 1,120                |
| Agriculture/livestock         | 200      | 0.446            | 0.415                    | 0.143                 | 2.76                             | 0.859                               | —               | 510                     | 1,308                |
| Forestry                      | 800      | 0.389            | 0.355                    | 0.136                 | —                                | 0.695                               | —               | 292                     | 904                  |

Read:

- Panel A shows large cross-industry variation in volatility and political sensitivities.
- Trade exposure is especially high in electronic and electrical equipment, and low in utilities and building-material sectors.
- Contract enforcement sensitivity is high for industries with complex input structures, such as construction.

This table reports the mean comparison tests (with unequal variances) of total return volatility between the sets of observations split according to elections, party orientation, autocracy, and political risk. For these tests, we use the entire sample of industry-country-year observations. The groups are: elections vs. no elections (Panel A); left party versus other parties (Panel B); high autocracy versus. low autocracy (Panel C); and high political risk vs. low political risk (Panel D). The numbers in parentheses are *p*-values. The coefficients significant at the 10% level (based on a two-tailed test) or higher are in boldface. All of the variables are defined in Table 1. *N* is the number of observations in each group. The high autocracy (low autocracy) group contains industry-country-year observations that belong to the top 75th percentile, autocracy > 2.9 (bottom 25th percentile, autocracy = 0), of the autocracy index. The high political risk (low political risk) group contains industry-country-year observations that belong to the top 75th percentile, political risk > 36.7 (bottom 25th percentile, political risk < 15.9), of the political risk index.

**Table 4**  
Volatility of industries exposed to international trade conditional on political variables

| Specification | Elections        |                          |                       | Autocracy        |                          |                       | Political risk   |                          |                       |

## 5.6 Table 5: contract enforcement sensitivity

Read:

- Industries more dependent on contract enforcement are more volatile during national elections.
- The election interaction coefficient is **0.0562** for total volatility, **0.0300** for idiosyncratic volatility, and **0.0914** for systematic volatility.
- Contract-sensitive industries are also more volatile when national political risk is high. The political-risk interaction coefficients are positive and significant for all three volatility measures.
- The autocracy interaction is negative and marginally significant for total and systematic volatility.
- The economic magnitude is meaningful. The paper's Canada/Brazil comparison implies that the relative volatility of a high-contract-sensitivity industry versus a lower-sensitivity industry is about **12.0%** larger in Canada but **26.8%** larger in Brazil.
- The table supports the institutional channel: political instability matters more when production depends on many contractual relationships.

**Table 5**  
Volatility of industries sensitive to contract enforcement conditional on political variables

| Specification                                                                                | Total volatility             | Idiosyncratic volatility     | Systematic volatility        |

This table reports the results of OLS regressions of the logs of total return volatility, idiosyncratic volatility, and systematic volatility on the interaction terms of industry contract enforcement sensitivity with national elections, autocracy, political risk, and control variables. All of the variables are defined in Table 1. Every regression includes industry, country, and year fixed effects. The numbers in parentheses are *p*-values. The coefficients significant at the 10% level (based on a two-tailed test) or higher are in boldface. \*, \*\*, \*\*\* indicate significance at the 10%, 5%, and 1% levels, respectively. Standard errors are clustered by countries and years to adjust for heteroscedasticity, cross-sectional, and time-series correlations.

**Table 6**  
Volatility of labor-intensive industries conditional on elections and party orientation

This table reports the results of OLS regressions of the logs of total return volatility, idiosyncratic volatility, and systematic volatility on the interaction terms of industry labor intensity with the left party orientation dummy variable, national elections dummy variable, and control variables. All of the variables are defined in Table 1. Every regression includes industry, country, and year fixed effects. The numbers in parentheses are *p*-values. The coefficients significant at the 10% level (based on a two-tailed test) or higher are in boldface. \*, \*\*, \*\*\* indicate significance at the 10%, 5%, and 1% levels, respectively. Standard errors are clustered by countries and years to adjust for heteroscedasticity, cross-sectional, and time-series correlation.

## 5.7 Table 6: labor intensity, elections, and left-party government

Read:

- Labor-intensive industries have higher volatility under left-party governments.
- The interaction between labor intensity and left-party orientation is **0.1609** for total volatility and **0.1920** for systematic volatility, both highly significant.
- The interaction with national elections is positive and marginally significant for total and systematic volatility.
- The idiosyncratic-volatility coefficients are not statistically significant in the main specification.
- The table implies that the labor channel is mostly a systematic-risk channel, not a firm-specific risk channel.
- The interpretation is that labor-market policy and labor adjustment costs affect broad cash-flow exposure for labor-intensive sectors.

## 5.8 Table 7: decomposition of left-party orientation

### Read:

- Table 7 addresses the concern that left-party governments are elected after poor economic outcomes.
- The authors first predict left-party orientation using lagged macro variables, then split party orientation into explained and unexplained components.
- The interaction of labor intensity with the unexplained component remains positive and significant for all three volatility measures.
- This supports the view that the labor-party result is not simply driven by past volatility or macroeconomic performance.

## 5.9 Table 8: labor intensity and employment rigidity

### Read:

- Table 8 uses a more direct labor-regulation measure: the World Bank rigidity of employment index.
- The interaction between labor intensity and employment rigidity is positive for total volatility and systematic volatility.
- The coefficients are **0.0581** for total volatility and **0.0778** for systematic volatility.
- This table strengthens the labor-channel interpretation because it uses a direct measure of employment regulation rather than only party orientation.

## 5.10 Robustness tests

### Read:

- The results survive instrumental-variable specifications for autocracy and political risk.

**Table 7**  
**Decomposition of left party orientation variable**

This table reports the results of OLS regressions of the logs of return volatility, idiosyncratic volatility, and systematic volatility on the interaction terms of labor intensity with unexplained and explained (by lagged macroeconomic variables) portions of party orientation and control variables. All of the variables are defined in Table 1. Every regression includes industry, country, and year fixed effects. The numbers in parentheses are  $p$ -values. The coefficients significant at the 10% level (based on a two-tailed test) or higher are in boldface. \*, \*\*, \*\*\* indicate significance at the 10%, 5%, and 1% levels, respectively. Standard errors are clustered by countries and years to adjust for heteroscedasticity, cross-sectional, and time-series correlations.

**Table 8**  
**Volatility of labor-intensive industries conditional on rigidity of employment index**

This table reports the results of OLS regressions of the logs of total return volatility, idiosyncratic volatility, and systematic volatility on the interaction term of industry labor intensity with country rigidity of employment index and control variables. The regressions are run using the panel of industry-country-year observations from 2004 to 2006. Every regression includes country, industry, and year fixed effects. All of the variables are defined in Table 1. The numbers in parentheses are  $p$ -values. The coefficients significant at the 10% level (based on a two-tailed test) or higher are in boldface. \*, \*\*, \*\*\* indicate significance at the 10%, 5%, and 1% levels, respectively. Standard errors are clustered by countries and years to adjust for heteroscedasticity, cross-sectional, and time-series correlations.

- They are not driven by early elections or flexible election systems.
- They survive controls for political crises and financial crises.
- They survive alternative volatility construction using size, debt, or diversification weights.
- They survive restricting the sample to pure-play firms.
- They survive controlling for ROA volatility, suggesting that market volatility is not merely a mechanical reflection of fundamental volatility.
- They survive using country-specific labor intensity from Worldscope.
- They survive including the three political sensitivities jointly, though the labor-intensity channel becomes somewhat less significant when all channels are included together.

## 6 Short summary

- **Method.** The paper uses a cross-country, cross-industry panel design that interacts industry political sensitivities with country political variables.
- **Measurement.** Political sensitivities are trade exposure, contract enforcement sensitivity, and labor intensity. Political variables include elections, autocracy, political risk, left-party orientation, and employment rigidity.

- **Main result.** Industries with higher political exposure become more volatile when the relevant political risk is high.
- **Domestic versus global risk.** Domestic political risk mainly affects systematic volatility, while foreign political risk transmitted through trade mainly affects idiosyncratic volatility.
- **Economic implication.** International trade can transmit foreign political risk, and industry input structure and labor dependence shape the volatility cost of political uncertainty.

## 7 Conclusion

### 7.1 Core conclusion

- The paper shows that political risk affects stock-return volatility, but not uniformly across industries.
- The transmission channels are economically intuitive: trade exposure, contract enforcement dependence, and labor intensity.
- Routine political events, such as elections and shifts in party orientation, can matter for financial volatility even outside dramatic crises.

### 7.2 Economic intuition

- Export-oriented industries are exposed to domestic trade-policy uncertainty and to political conditions in trading-partner countries.
- Contract-dependent industries are exposed to political shocks that affect institutional quality and the reliability of supplier relationships.
- Labor-intensive industries are exposed to political shifts in labor regulation and employment protection.
- Domestic political risk affects broad market factors and therefore systematic volatility, while foreign political shocks through trade are harder to diversify fully and appear more in idiosyncratic volatility.

### 7.3 Takeaway

This paper turns the broad idea that “politics affects markets” into a structured industry-level empirical design. The key lesson is that political risk is transmitted through specific economic exposures. A firm’s industry determines whether political events show up mainly as systematic risk, idiosyncratic risk, or both. For investors, the paper implies that political-risk management should account for industry trade links, input complexity, and labor dependence. For firms, it implies that decisions about exporting, supply-chain complexity, and labor-intensive production can affect the volatility of cash flows and the cost of capital.
